The "Ideal" Low-Pass Filter

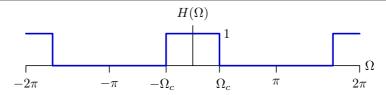

Consider a system characterized by the following purely real frequency response:

Such a system is called a **low-pass filter**, because it allows low frequencies to pass through unmodified, while attenuating high frequencies.

We could apply this filter to a signal by multiplying the DTFT of that signal by the values above. But we could also apply the filter by operating in the time domain.

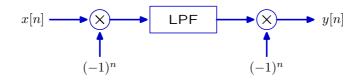

The "Ideal" Low-Pass Filter

We can apply this filter to a signal by convolving with its unit sample response. What is the unit sample response of the system whose frequency response is shown above?

$$h[n] = \frac{1}{2\pi} \int_{2\pi} H(\Omega) e^{j\Omega n} d\Omega$$
$$= \frac{1}{2\pi} \int_{-\Omega_c}^{\Omega_c} e^{j\Omega n} d\Omega$$
$$= \frac{1}{2\pi} \frac{1}{jn} e^{j\Omega n} \Big|_{\Omega = -\Omega_c}^{\Omega_c}$$
$$= \frac{\sin(\Omega_c n)}{\pi n}$$

Consider the following system, where LPF represents a lowpass filter of the form discussed on the previous slides.

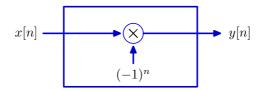

How many of the following statements are true?

- The transformation from x[n] to y[n] is linear.
- The transformation from x[n] to y[n] is time invariant.
- The transformation from x[n] to y[n] is a high-pass filter.

Consider Each Part Separately

Start with the multiplier.

Is the following system linear?

Assume the response to the input $x_1[n]$ is $y_1[n]$ and the response to the input $x_2[n]$ is $y_2[n]$. Calculate the response to $x[n] = \alpha x_1[n] + \beta x_2[n]$.

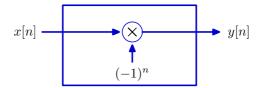

$$y[n] = (-1)^n x[n]$$

= $(-1)^n (\alpha x_1[n] + \beta x_2[n])$
= $\alpha (-1)^n x_1[n] + \beta (-1)^n x_2[n]$
= $\alpha y_1[n] + \beta y_2[n]$

∴ linear!

Consider Each Part Separately

Is this system time-invariant?

Assume the response to the input $x_1[n]$ is $y_1[n]$. Calculate the response to $x[n] = x_1[n - n_0]$.

$$y[n] = (-1)^n x[n]$$

= $(-1)^n x_1[n - n_0]$
= $(-1)^{n_0} (-1)^{n - n_0} x_1[n - n_0]$
= $(-1)^{n_0} y_1[n - n_0]$

Shifting the input by n_0 samples shifts does not just shift the output by n_0 samples.

∴ this system is not time-invariant!

Consider Each Part Separately

Is the LPF linear? time-invariant?

The defining property of a **filter** is that its output is a weighted sum of (possibly) shifted versions of the frequencies in the input, so that

$$Y(\Omega) = H(\Omega)X(\Omega) \,.$$

Multiplication in frequency is the same as convolution in time, so

$$y[n] = (x * h_L)[n]$$

where $h_L[\cdot]$ represents the unit-sample response of the filter.

Convolution is both linear and time invariant (as shown on the next slides).

Convolution is Linear

Assume the response to the input $x_1[n]$ is $y_1[n]$ and the response to the input $x_2[n]$ is $y_2[n]$. Calculate the response to $x[n] = \alpha x_1[n] + \beta x_2[n]$.

$$y[n] = \sum_{m=-\infty}^{\infty} x[m]h[n-m]$$

=
$$\sum_{m=-\infty}^{\infty} \left(\alpha x_1[m] + \beta x_2[m]\right)h[n-m]$$

=
$$\alpha \sum_{m=-\infty}^{\infty} x_1[m]h[n-m] + \beta \sum_{m=-\infty}^{\infty} x_2[m]h[n-m]$$

=
$$\alpha y_1[n] + \beta y_2[n]$$

∴ linear!

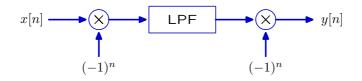

Convolution is Time-Invariant

Assume the response to the input $x_1[n]$ is $y_1[n] = (x_1 * h)[n]$. Calculate the response to $x[n] = x_1[n-n_0]$.

$$\begin{split} y[n] &= (x * h)[n] \\ &= \sum_{m=-\infty}^{\infty} x[m]h[n-m] \\ &= \sum_{m=-\infty}^{\infty} x_1[m-n_0]h[n-m] \\ &= \sum_{l=-\infty}^{\infty} x_1[l]h[n-(n_0+l)] \\ &= \sum_{l=-\infty}^{\infty} x_1[l]h[(n-n_0)-l] \\ &= (x_1 * h)[n-n_0] = y_1[n-n_0] \end{split}$$

∴ time-invariant!

This system is the cascade of three linear subsystems, two of which are time varying.

Thus we know that the composite system is linear.

- The transformation from x[n] to y[n] is linear. $\sqrt{}$
- The transformation from x[n] to y[n] is time invariant.
- The transformation from x[n] to y[n] is a high-pass filter.

The first is true. Not sure about the others.

Could the cascade of two time-varying systems be time-invariant?

Yes. Think about the cascade of $\times (-1)^n$ with $\times (-1)^n$.

w

z

y

Determine an expression for y[n] in terms of x[n] using a time-domain approach. Assume that the unit sample response of the LPF is $h_L[n]$.

$$x[n] \xrightarrow{w[n]} LPF \xrightarrow{z[n]} \xrightarrow{y[n]} y[n]$$

$$(-1)^{n} (-1)^{n} (-1)^{n}$$

$$[n] = (-1)^{n}x[n]$$

$$[n] = (w * h_{L})[n] = \sum_{m=-\infty}^{\infty} (-1)^{m}x[m]h_{L}[n-m]$$

$$[n] = (-1)^{n}z[n] = (-1)^{n}\sum_{m=-\infty}^{\infty} (-1)^{m}x[m]h_{L}[n-m]$$

$$= \sum_{m=-\infty}^{\infty} (-1)^{n+m}x[m]h_{L}[n-m] = \sum_{m=-\infty}^{\infty} (-1)^{n-m}x[m]h_{L}[n-m]$$

$$= (x * h_{H})[n] \text{ where } h_{H}[n] = (-1)^{n}h_{L}[n]$$

Find an expression for the unit sample response of a lowpass filter that passes frequencies in the range $-\Omega_c < \Omega < \Omega_c$.

$$H_{L}(\Omega)$$

$$H_{L}(\Omega)$$

$$H_{L}[n] = \frac{1}{2\pi} \int_{2\pi} H_{L}(\Omega) e^{j\Omega n} d\Omega$$

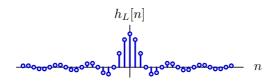

$$= \frac{1}{2\pi} \int_{-\Omega_{c}}^{\Omega_{c}} e^{j\Omega n} d\Omega$$

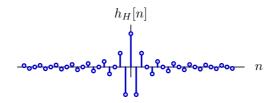

$$= \frac{1}{2\pi} \left[\frac{e^{j\Omega n}}{jn} \right]_{-\Omega_{c}}^{\Omega_{c}}$$

$$= \frac{\sin(\Omega_{c} n)}{\pi n}$$

: $h_H[n] = (-1)^n h_L[n] = (-1)^n \frac{\sin(\Omega_c n)}{\pi n}$

Plot $h_L[n]$ and $h_H[n]$ for $\Omega_c = \frac{\pi}{3}$.

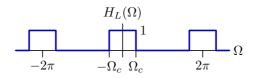

Determine an expression for $H_H(\Omega)$.

$$H_H(\Omega) = \sum_{n=-\infty}^{\infty} h_H[n] e^{-j\Omega n}$$
$$= \sum_{n=-\infty}^{\infty} (-1)^n h_L[n] e^{-j\Omega n}$$
$$= \sum_{n=-\infty}^{\infty} e^{j\pi n} h_L[n] e^{-j\Omega n}$$
$$= \sum_{n=-\infty}^{\infty} h_L[n] e^{-j(\Omega - \pi)n}$$
$$= H_L(\Omega - \pi)$$

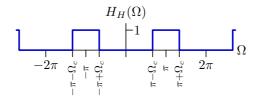

This is an example of the frequency shifting property:

If
$$x[n] \stackrel{\text{DTFT}}{\Rightarrow} X(\Omega)$$
 then $e^{j\Omega_o n} x[n] \stackrel{\text{DTFT}}{\Rightarrow} X(\Omega - \Omega_o).$

Plot $H_H(\Omega)$. Compare to $H_L(\Omega)$.

 $H_H(\Omega) = H_L(\Omega - \pi)$

 $H_H(\Omega)$ is a highpass filter!

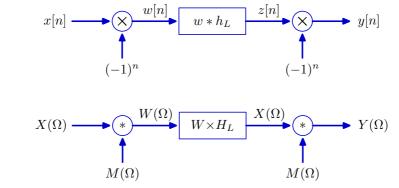

We have just shown that the original system is a highpass system.

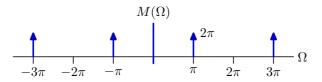

Therefore all of the following are true!

- The transformation from x[n] to y[n] is linear. $\sqrt{}$
- The transformation from x[n] to y[n] is time invariant. $\sqrt{}$
- The transformation from x[n] to y[n] is a high-pass filter. $\sqrt{}$

Alternatively, we could solve this problem in the frequency domain.

Since $(-1)^n = e^{j\pi n}$, $M(\Omega)$ is a complex sinusoid with frequency π .

Assume $X(\Omega)$ differs at high and low frequencies, as shown below.

Convolving with $M(\Omega)$ shifts $X(\Omega)$ by $\Omega=\pi$:

I

$$W(\Omega)$$
: -2π $-\pi$ 0 π 2π Ω

Low pass filtering removes the high frequencies. Assume $\Omega_c = \pi/2$:

Convolving with $M(\Omega)$ shifts the result by $\Omega = \pi$:

 $Y(\Omega)$ is a highpass version of $X(\Omega)$.
